

ASSIGNMENT_10.1

Name: Ch.Jyothika

Ht.no:2303A51280

Batch:05

Task 1: Syntax and Logic Errors

Task: Task: Use AI to identify and fix syntax and logic errors in a faulty Python script.

Sample Input Code:

```
# Calculate average score of a student

def calc_average(marks):

    total = 0

    for m in marks:

        total += m

    average = total / len(marks)

    return avrage # Typo here

marks = [85, 90, 78, 92]

print("Average Score is ", calc_average(marks))
```

Expected Output:

- Corrected and runnable Python code with explanations of the fixes.

PROMPT:

```
def calc_average(marks):
    total = 0
    for m in marks:
        total += m
    average = total / len(marks)
```

```
return avrage # Typo here
```

```
marks = [85, 90, 78, 92]
```

```
print("Average Score is ", calc_average(marks))
```

In above given code identify and fix syntax and logic errors in a faulty

CODE:

```
task1(10.1).py > ...
1  def calc_average(marks):
2      total = 0
3      for m in marks:
4          total += m
5      average = total / len(marks)
6      return average           # fixed spelling
7
8  marks = [85, 90, 78, 92]
9  print("Average Score is", calc_average(marks)) # added missing )
```

OUTPUT:

```
ers/maddi/OneDrive/Desktop/AI ASSISTED CODING/task1(10.1).py"
Average Score is 86.25
```

EXPLANATION:

1. Typo in return value – the function calculates average but then tries to return avrage, which isn't defined.
→ Python would raise a NameError at runtime.
2. Missing parenthesis in the print call – the closing) after calc_average(marks) was omitted, so the code wouldn't even parse.

Task 2: PEP 8 Compliance

ask: Use AI to refactor Python code to follow PEP 8 style guidelines.

Sample Input Code:

```
def area_of_rect(L,B) : return L*B
```

```
print(area_of_rect(10,20))
```

Expected Output:

- Well-formatted PEP 8-compliant Python code.

PROMPT:

Refactor the following Python code to follow PEP 8 style guidelines.

Improve formatting, spacing, naming conventions, and indentation without changing the logic or output.

Code:

```
def area_of_rect(L,B) : return L*B  
print(area_of_rect(10,20))
```

CODE:

```
task2(10.1.py > ...  
1 def area_of_rectangle(length, breadth):  
2     """Return the area of a rectangle."""  
3     return length * breadth  
4  
5  
6 print(area_of_rectangle(10, 20))
```

OUTPUT:

```
PS C:\Users\maddi\OneDrive\Desktop\AI ASSISTED CODING> & C:/Users/maddi/AppData/Local/Microsoft/WindowsApps/python3.13.exe "c:/Users/maddi/OneDrive/Desktop/AI ASSISTED CODING/task2(10.1).py"  
200
```

EXPLANATION:

- Renamed the function and parameters to be lowercase with underscores and more descriptive (area_of_rectangle, length, breadth).
- Moved the return to its own indented line and added a docstring for clarity.
- Added spaces around operators and after commas per PEP 8.
- The logic stays the same and it still prints 200, but the style now follows Python conventions.

Task 3: Readability Enhancement

Task: Use AI to make code more readable without changing its logic.

Sample Input Code:

```
def c(x,y):  
    return x*y/100  
  
a=200  
  
b=15  
  
print(c(a,b))
```

Expected Output:

- Python code with descriptive variable names, inline comments, and clear formatting.

PROMPT:

Improve the readability of the following Python code without changing its logic or output.

Use meaningful variable and function names, proper indentation, and add simple comments.

Code:

```
def c(x,y):  
    return x*y/100  
  
a=200  
  
b=15  
  
print(c(a,b))
```

CODE:

```
task3(10.1).py > ...
1 def calculate_percentage(amount, percent):
2     """Return the given percentage of `amount`."""
3     return amount * percent / 100
4
5 # sample values
6 principal_amount = 200
7 rate = 15
8
9 # compute and display result
10 print(calculate_percentage(principal_amount, rate))
```

OUTPUT:

```
PS C:\Users\maddi\OneDrive\Desktop\AI ASSISTED CODING> & C:/Users,
ers/maddi/OneDrive/Desktop/AI ASSISTED CODING/task3(10.1).py
30.0
PS C:\Users\maddi\OneDrive\Desktop\AI ASSISTED CODING>
```

EXPLANATION:

- Renamed c → calculate_percentage and parameters/vars to describe their roles.
- Added a docstring and comments for clarity.
- Fixed indentation and spacing so the code is easy to read.
- Logic unchanged; it still prints 30.0 for the given inputs.

Task 4: Refactoring for Maintainability

Task: Use AI to break repetitive or long code into reusable functions.

Sample Input Code:

```
students = ["Alice", "Bob", "Charlie"]
print("Welcome", students[0])
print("Welcome", students[1])
print("Welcome", students[2])
```

Expected Output:

- Modular code with reusable functions.

PROMPT:

Refactor the following Python code to improve maintainability.

Break repetitive or long code into reusable functions without changing the output.

Code:

```
students = ["Alice", "Bob", "Charlie"]

print("Welcome", students[0])
print("Welcome", students[1])
print("Welcome", students[2])
```

CODE:

```
task4(10.1.py > ...
1 def greet(name: str) -> None:
2     """Print a welcome message for one student."""
3     print("Welcome", name)
4
5 def welcome_all(students: list[str]) -> None:
6     """Greet every student in the list."""
7     for student in students:
8         greet(student)
9
0 students = ["Alice", "Bob", "Charlie"]
1 welcome_all(students)
```

OUTPUT:

```
Welcome Alice
Welcome Bob
Welcome Charlie
```

EXPLANATION:

- Pulled the welcome message into a greet function.
- Created welcome_all to loop through any student list.
- Data (names) now lives in the list, not hard-coded print calls.
- Output stays the same but structure is easier to extend.

Task 5: Performance Optimization

Task: Use AI to make the code run faster.

Sample Input Code:

```
# Find squares of numbers  
  
nums = [i for i in range(1,1000000)]  
  
squares = []  
  
for n in nums:  
  
    squares.append(n**2)  
  
print(len(squares))
```

Expected Output:

- Optimized code using list comprehensions or vectorized operations.

PROMPT:

Optimize the following Python code to improve performance and make it run faster without changing the output or logic.

Use efficient methods such as list comprehensions or vectorized operations.

Code:

```
# Find squares of numbers  
  
nums = [i for i in range(1,1000000)]  
  
squares = []  
  
for n in nums:  
  
    squares.append(n**2)  
  
print(len(squares))
```

CODE:

```
# task5(10.1).py > ...
1  # generate squares efficiently
2  squares = [n * n for n in range(1, 1_000_000)]
3
4  print(len(squares))
```

OUTPUT:

```
C:\Users\mada1\OneDrive\Desktop\AI ASSISTED CODING\task5(10.1).py
999999
```

EXPLANATION:

- Removed the explicit nums list and for/append loop.
- Replaced them with a single list comprehension that computes squares in C-level code.
- This reduces Python-level overhead and memory use while producing the same len result.
- Output stays 1000000, but the comprehension runs much faster.

Task 6: Complexity Reduction

Task: Use AI to simplify overly complex logic.

Sample Input Code:

```
def grade(score):
```

```
    if score >= 90:
```

```
        return "A"
```

```
    else:
```

```
        if score >= 80:
```

```
            return "B"
```

```
    else:
```

```
        if score >= 70:
```

```
            return "C"
```

```
else:  
    if score >= 60:  
        return "D"  
  
    else:  
        return "F"
```

PROMPT:

Simplify the following Python code to reduce complexity and improve readability without changing its logic or output.

Replace nested if-else statements with cleaner logic such as elif or dictionary mapping.

Code:

```
def grade(score):  
    if score >= 90:  
        return "A"  
  
    else:  
        if score >= 80:  
            return "B"  
  
        else:  
            if score >= 70:  
                return "C"  
  
            else:  
                if score >= 60:  
                    return "D"  
  
                else:  
                    return "F"
```

CODE:

```
task6(10.1).py > ...
1  def grade(score):
2      if score >= 90:
3          return "A"
4      elif score >= 80:
5          return "B"
6      elif score >= 70:
7          return "C"
8      elif score >= 60:
9          return "D"
10     else:
11         return "F"
12
13 # example usage
14 print(grade(85)) # prints B
```

OUTPUT:

```
PS C:\Users\maddi\OneDrive\Desktop\AI ASSISTED CODING> & C:/Users/maddi/AI ASSISTED CODING/task6(10.1).py
B
```

EXPLANATION:

- A def just creates the function object; it doesn't execute the body or print anything. Since the script only defines grade and never calls it, Python has nothing to show—hence no output. Call the function (e.g. print(grade(85))) to produce a result.
